Received July 30, 1999

Four new bioactive pyridinium alkaloids, named spongidines A–D (**5–8**), have been isolated from a Vanuatu sponge of the genus *Spongia*, together with known petrosaspongiolides D (**1**) and G (**2**). Compounds **3** and **4** are 21-hydroxy derivatives of petrosaspongiolides K and P. Structure elucidation was accomplished through extensive 2D NMR experiments (COSY, ROESY, HMBC, HMQC) and IR, UV, and FABMS data. All compounds significantly inhibited human synovial phospholipase A₂ (PLA₂) at 10 μ M, with an IC₅₀ value of 5.8 μ M for compound **4**, which is the most potent inhibitor, with a higher selectivity toward this enzyme than the reference inhibitor manolide. Pyridinium alkaloids (**5–8**) mainly inhibited human synovial PLA₂. Compound **8**, which contains a sulfonic acid group, is the most interesting inhibitor.

Marine sponges of the genus *Spongia* have been extensively investigated and have gained importance for their high content of malonate-derived metabolites¹ with a variety of biological activities. A broad array of sesquiterpenoids, diterpenoids, and sesterterpenoids^{2–4} have also been isolated from other Dictyoceratida and Dendroceratida sponges and soft corals. Potent antiinflammatory agents^{5–7} are sesterterpenes with some structural features, like a γ -hydroxy-butenolide moiety, exemplified by the monocarbocyclic manolide⁸ and by the tricarbocyclic luf-folide,⁹ which are inhibitors of various secreted forms of phospholipase A₂ (PLA₂).¹⁰

In our ongoing research program on new bioactive metabolites from Vanuatu Islands marine invertebrates, we found significant activity in the chloroform extracts of a sponge of the genus *Spongia* (family Spongiidae; order Dictyoceratida). Along with the major metabolites petrosaspongiolides D (**1**) and G (**2**) recently reported in the sponge *Petrosaspongia nigra* (Dictyoceratida),^{11,12} we isolated six new metabolites. Two of them are closely related to petrosaspongiolides K¹² and P¹³ (**3** and **4**), and four are new pyridinium alkaloids (**5–8**) named spongidines A–D.

Herein we report their isolation, structure elucidation, and the data of their in vitro tests on the inhibition of five different secretory PLA₂ (sPLA₂), belonging to the groups I (*Naja naja* venom and porcine pancreatic enzymes), II (human synovial recombinant enzyme), and III (bee venom enzyme), as well as on cytosolic PLA₂ (cPLA₂), from macrophage line RAW 264.7 (group IV), using manolide as reference inhibitor. None of these compounds exerted cytotoxic effects on human neutrophils at the concentrations tested (see Table 3).

Results and Discussion

Freeze-dried specimens (1.0 kg), collected near Tongoa (Vanuatu Islands) were extracted with MeOH. The methanol extract was subjected to Kupchan's partitioning methodology.¹⁴ The chloroform-soluble material was then fractionated by DCCC using CHCl₃–MeOH–H₂O (7:13:8) followed by reversed-phase HPLC (MeOH–H₂O, 7:3) to yield compounds **3–8** and a large amount of the previously

isolated petrosaspongiolides D (**1**) and G (**2**). The identity of the known compounds was established by comparison of their spectral properties with authentic samples.¹²

21-Hydroxy petrosaspongiolide K (**3**), showed in the FABMS spectrum (positive ion), a molecular ion peak at m/z 389 ($\text{M} + \text{H}$)⁺, 16 mass units more than petrosaspongiolide K isolated from *Petrosaspongia nigra*.¹² The presence of an α,β -unsaturated ketone was supported by UV (λ_{max} 235 nm; ϵ = 5450). NMR data were very similar to those of petrosaspongiolide K except for one tertiary methyl proton signal replaced by an AB system at δ_{H} 3.73 and 3.38 (2H, AB system, J = 12.0 Hz, H₂-21), indicating that **3** is a hydroxy-derivative of petrosaspongiolide K.¹² The protonated carbon signals were first assigned from HMQC data, and then an HMBC experiment revealed long-range coupling between the H-5 proton signal at δ_{H} 1.02 and carbon signals at δ_{C} 65.0 (C-21) and 17.6 (C-22). The signal of H₂ protons at C-21 (δ_{H} 3.73 and 3.38) showed correlations to the C-20 (δ_{C} 27.8), C-3 (δ_{C} 36.8), C-4 (δ_{C} 40.0), and C-5 (δ_{C} 58.8). These correlations confirm that the signal at δ_{C} 65.0 is due to C-21 and that the oxymethylene is joined to C-4. (^1H and ^{13}C NMR are given in the Experimental Section.)

21-Hydroxy petrosaspongiolide P (**4**) had a molecular formula $\text{C}_{25}\text{H}_{38}\text{O}_6$ as established by HRFABMS. Analysis

^a Results show percentages of inhibition at 10 μM and IC₅₀ (μM) values determined only for those compounds that reach 50% of inhibition. Mean \pm S.E.M. (n = 6). ^b RAP: Rat air-pouch PLA₂. ^c p < 0.05; ^d p < 0.01.

of the ^1H and ^{13}C NMR spectra revealed the presence of two interconverting species formed by a tricyclic carbon framework in its structure, as observed in terpenoids, and a γ -hydroxybutenolide unit. NMR data are consistent with those reported for petrosaspongiolide P,¹³ which revealed the typical hemiacetal functionality of the γ -hydroxybutenolide ring with an additional hemiacetal function in the molecule. The only significant differences in the NMR data were for signals corresponding to ring A. The upfield shift of C-3 (δ_{C} 36.7 ppm) and the presence of an oxygenated methylene carbon at δ_{C} 65.1 are consistent with a hydroxyl group at C-21. (^1H and ^{13}C NMR are given in the Experimental Section.)

Spongidine A (**5**) had a molecular formula of $\text{C}_{23}\text{H}_{34}\text{NO}_2$ as established by HRFABMS (m/z 356.2499; calcd 356.2590) and NMR data. The FAB (positive ion) showed a fragment peak at m/z 312 (loss CO_2), thereby indicating the presence of a carboxyl group. The ^1H NMR spectrum exhibited signals for four methyl singlets (δ_{H} 0.93 \times 2, 1.04, and 1.32), three aromatic protons (δ_{H} 7.90, d, J = 6.3 Hz; δ_{H} 8.49 d, J = 6.3 Hz, and δ_{H} 8.53 s), and a methylene proton signal at δ_{H} 5.07 (s) (Table 1).

The ^{13}C NMR (Table 1) spectrum revealed 23 carbons, including signals for one carboxyl group (170.5 ppm), four quaternary methyls (33.8, 25.6, 21.9, and 16.8 ppm), and three quaternary carbons (40.5, 40.0, and 34.3 ppm), consistent with a tricyclic skeleton with a *gem*-dimethyl group at C-4 and two methyl groups at the ring junction C-8 and C-10. In the ^{13}C NMR spectrum are also detectable five aromatic carbons, two quaternary (170.2 and 137.7 ppm) and three CH (146.3, 143.3 and 124.7 ppm), implying the presence of a disubstituted pyridinium salt. The UV [λ_{max} 267 nm, 273 (sh) and 212] and the IR (1637 cm^{-1}) spectra exhibited absorption characteristic of an alkylpyridinium salt.¹⁵ The large, broad absorption at 1637 cm^{-1} was also due to the presence of a carboxylate group as shown by ^{13}C NMR data. Inspection of the COSY spectrum allowed us to assemble three partial structure units: C-1 to C-3, C-5 to C-7, and C-9 to C-12. The H₂-12 protons, downfield shifted at δ_{H} 2.97 and δ_{H} 3.15, are typical for a benzylic methylene, indicating that the pyridinium moiety was fused to tricyclic skeleton at C-13 and C-14. In the HMBC experiment this was supported by cross-peaks: H-15/C-8, C-13, C-16; H-21/C-14, C-16, C-13, C-12; H-16/C-14, C-15, C-21. The remaining methylene protons at δ_{H} 5.07 were long-range coupled to the C-16, C-21 and to the carboxylic group (Table 1).

Spongidine B (**6**) had a molecular formula of $\text{C}_{25}\text{H}_{36}\text{NO}_4$, $\text{C}_2\text{H}_2\text{O}_2$ larger than **5** as shown in the FAB (positive ion) at m/z 414 [M]⁺. ^1H and ^{13}C NMR data were quite similar to those of **5**, except for the lack of a methyl group replaced by an acetoxymethyl group in **6**. A significant downfield shift of C-4 (δ_{C} 38.2 vs. 34.3 ppm in **5**) and an upfield shift

of C-3 (δ_C 37.4 ppm vs. 43.2 in **5**) and C-18 (δ_C 27.8 ppm vs. 21.9 in **5**) implied the presence of an acetoxymethyl group at C-4 (δ_H 4.36–3.98, AB system, $J = 11.0$ Hz, CH_2) resonating in the ^{13}C NMR at 68.2 ppm. The stereochemistry at C-4 was established by a ROESY experiment. The acetoxymethyl group was assigned as axial because of intense cross-peaks between the H₂-17 protons and the angular methyl protons at C-19 (δ_H 1.04). (For NMR data, see Experimental Section.)

Spongidine C (**7**) showed a molecular ion peak at m/z 428 in the FAB (positive ion), in agreement with the composition $C_{26}H_{38}NO_4$ (72 mass units more than **5**). The UV and IR spectra were suggestive of an alkylpyridinium salt, as observed in spongidines A (**5**) and B (**6**). Analysis of 1H and ^{13}C NMR spectra and interpretation of 1H - 1H COSY data established the relationship between **7** and spongidines A (**5**) and B (**6**). All signals assigned to rings A, B, and C, and the glycine residue in the 1H NMR spectrum were present, whereas in the aromatic region a signal of the pyridinium system was missing. Two aromatic protons resonating as singlets (δ_H 8.42 and 7.81) are detectable, implying a trisubstituted pyridinium salt. Inspection of the COSY spectrum showed two methylene proton signals at δ_H 3.20 (t, $J = 6.8$) and 2.68 (t, $J = 6.8$) mutually coupled. This latter exhibited, in the HMBC experiment, a cross-peak with a carbonyl signal at 179.4 ppm, which allowed constructing a propionic side chain. The observation that the C-24 aromatic proton and C-18 methylene proton exhibited HMBC interaction with C-16 (δ_C 157.4) helped to locate the side chain at C-16 of a pyridinium moiety. This compound is apparently a 25-norsesterterpene derived by condensation with glycine of a 16-keto-24-al precursor.¹²

The HRFABMS of **8** showed a molecular ion peak at m/z 406.2366, in agreement with the molecular formula $C_{23}H_{36}NO_3S$ (calcd 406.2416). 1H and ^{13}C NMR data of **8** are superimposable on those of **5** for the tricyclic carbon system, but significantly different NMR shifts are seen for the signals of the pyridinium salt. Inspection of the COSY spectrum showed two methylene triplets at δ_H 4.88 ($J = 6.2$ Hz) and δ_H 3.43 ($J = 6.2$ Hz) mutually coupled, showing correlation by HMQC with carbon signals at δ_C 57.5 and 51.1, respectively. The IR spectrum contained an absorbance at 1637 cm^{-1} , typical for an alkylpyridinium salt, and two strong bands at 1216 and 1048 cm^{-1} , suggestive of a sulfonic acid salt.¹⁶ All these data suggested the presence of a taurine residue. The HMBC data (Table 2) showed cross-peaks $-CH_2-CH_2-SO_3H/C-21, C-16$ and $-CH_2-CH_2-SO_3H$, which imply that the taurine moiety is bonded to the pyridinium ring through the nitrogen atom.

Sesterterpenes with a γ -hydroxybutenolide moiety have received special attention after the discovery of manolide,⁸ a potent antiinflammatory agent that binds and blocks the enzyme PLA₂ through the formation of a covalent inhibitor-enzyme adduct.¹⁷ Two main groups of PLA₂ enzymes have been reported,¹⁸ the secretory PLA₂ (sPLA₂ groups I, II, III, V, IX, and X with a relatively small molecular weight) and the cytosolic PLA₂ (cPLA₂ groups IV, VI, VII, and VIII with a higher molecular weight). They also differ in Ca²⁺ requirements and molecular characteristics. It is well-known that inhibition of specific PLA₂ constitutes a potentially useful approach for treating a great variety of inflammatory disorders such as septic shock, adult respiratory distress syndrome, arthritis, and acute pancreatitis. Unfortunately, no potent and absolutely type-specific PLA₂ inhibitors are widely available. Recently, petrosaspongiolides M–R, isolated from *Petrosaspongia nigra*,¹³ have been

1 R=CH₂OH R'=OAc Petrosaspongiolide D

2 R=CH₂OH R'=OH Petrosaspongiolide G

5 R=CH₃ Spongidine A

6 R=CH₂OAc Spongidine B

8 Spongidine D

7 Spongidine C

tested in vitro on PLA₂ from different sources, where they showed a high degree of specificity toward human synovial PLA₂. Compounds **3**–**8** have been tested under the same experimental conditions on five different sPLA₂¹⁸ belonging to the groups I (*Naja naja* venom and porcine pancreatic enzymes), II (human synovial recombinant and rat air-pouch secretory enzymes¹⁹), and III (bee venom enzyme). Among petrosaspongiolide derivatives, compound **4** inhibited preferentially human synovial PLA₂ in the μM range (Table 3), showing a slightly lower potency toward this enzyme than that of the reference inhibitor, manolide. In contrast, compounds **3**–**8** had no inhibitory effects on cPLA₂, although this enzyme was partially inhibited by manolide at $10\text{ }\mu M$ (44.6 ± 5.6 of inhibition, mean \pm SEM, $n = 6$).

It is interesting to note that pyridinium alkaloids **5**–**8** inhibited mainly human synovial PLA₂ at $10\text{ }\mu M$. Among them, compound **8**, containing a sulfonic acid group, can be considered the most interesting inhibitor. In this regard, these pyridinium alkaloids can offer new structural requirements for further studies about mechanistic interactions between PLA₂ enzymes and inhibitors as it has been described for manolide-like sesterterpene molecules.²⁰ None of the pyridinium alkaloids (**5**–**8**) inhibited cPLA₂ (data not shown).

On the other hand, compounds **3**–**8** were devoid of significant cytotoxic effects on human neutrophils at concentrations up to $10\text{ }\mu M$, as assessed by the mitochondrial-dependent reduction of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide to formazan (data not shown).

Experimental Section

General Experimental Procedures. NMR spectra were obtained on a Bruker AMX-500 (1H at 500 MHz, ^{13}C at 125

MHz) instrument, with δ (ppm), J in Hz, and spectra referred to CD₃OD as internal standard. MS were recorded with a VG PROSPEC instrument equipped with a FAB source (Cs⁺ ion bombardment), using a glycerol or glycerol–thioglycerol (3:1) matrix. Optical rotations were measured on a Perkin-Elmer 141 polarimeter. Reversed-phase HPLC were performed on a C₁₈ μ -Bondapak column (30 cm \times 3.9 mm i.d.; flow rate 2 mL min⁻¹); Waters model 6000 A pump equipped with U6K injector and a differential refractometer, model 401; DCCC, on a DCC-A apparatus manufactured by Tokyo Rikakikai Co., equipped with 250 tubes.

Chemicals and Enzymes. Human synovial recombinant PLA₂ were kindly provided by Zeneca Pharmaceuticals, Macclishoph, Cheshire, U.K. Both [9,10-³H]oleic acid and 1-3-phosphatidylcholine 1-palmitoyl-2-arachidonoyl [arachidonoyl-1-¹⁴C] were purchased from Du Pont (Itisa, Madrid, Spain). The rest of the reagents were from Sigma Chemicals (St. Louis, MO). *E. coli* strain CECT 101 was a gift from Prof. Uruburu, Department of Microbiology, University of Valencia, Spain.

Assay of sPLA₂. sPLA₂ was assayed by using a modification of the method of Franson et al.²¹ *E. coli* strain CECT 101 was seeded in medium containing 1% tryptone, 0.5% NaCl, and 0.6% sodium dihydrogen orthophosphate, pH 5.0, and grown for 6–8 h at 37 °C in the presence of 5 μ Ci/mL [³H]oleic acid (sp. act. 10 Ci/mmol). After centrifugation at 2500 $\times g$ for 10 min, the cells were washed in buffer [0.7 M Tris–HCl, 10 mM CaCl₂, 0.1% bovine serum albumin (BSA) pH 8.0], resuspended in saline, and autoclaved for 30 to 45 min. At least 95% of the radioactivity was incorporated into phospholipids. *Naja naja* venom enzyme, porcine pancreatic enzyme, human recombinant synovial enzyme, and bee venom enzyme were diluted in 10 μ L of 100 mM Tris–HCl and 1 mM CaCl₂ buffer, pH 7.5. Supernatants (10 μ L) of exudates from zymosan-injected rat air-pouch¹⁸ were also used as a source of sPLA₂. Enzymes were preincubated at 37 °C for 5 min with 2.5 μ L of test compound solution or its vehicle in a final volume of 250 μ L. Incubation proceeded for 15 min in the presence of 10 μ L of autoclaved oleate-labeled membranes and was terminated by addition of 100 μ L ice-cold solution of 0.25% BSA in 100 mM Tris–HCl and 1 mM CaCl₂ buffer, pH 7.5, to a final concentration of 0.07% w/v. After centrifugation at 2500 $\times g$ for 10 min at 4 °C, the radioactivity in the supernatants was determined by liquid scintillation counting.

Assay of cPLA₂. cPLA₂ activity was measured as the release of radiolabeled arachidonic acid according to the method of Clark et al.²² using cytosolic fractions of murine monocyte cell line RAW 264.7 as the source of enzyme and 1-palmitoyl-2-[¹⁴C] arachidonoyl-*sn*-glycero-3-phosphocholine (57.0 mCi/mmol, 2 \times 10⁶ cpm) as substrate. Test compounds were dissolved in methanol and added to the reaction mixture just before the addition of the enzyme solution. The final concentration of methanol in the reaction mixture was less than 1%, which showed no effect on the enzyme activity. The reaction was stopped after a 60-min incubation period at 37 °C by mixing with 0.5 mL of isopropyl alcohol–heptane–0.5 M H₂SO₄ (10:5:1). Heptane (0.7 mL) and water (0.2 mL) were then added, and the solution was vigorously mixed for 15 s. The heptane phase was mixed with 100 mg of Si gel 60 (Merck, 70–230 mesh) and centrifuged, and the radioactivity in each supernatant was measured.

Cytotoxicity Assays. The mitochondrial-dependent reduction of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) to formazan²³ was used to assess the possible cytotoxic effects of test compounds on human neutrophils.

Statistical Analysis. The results are presented as mean \pm SEM. Inhibitory concentration 50% (IC₅₀) values were calculated from at least four significant concentrations ($n = 6$). The level of statistical significance was determined by analysis of variance (ANOVA), followed by Dunnett's *t*-test for multiple comparisons.

Animal Material. The sponge was collected near Tongoa (Vanuatu Islands) in 1996, and identified only to the genus *Spongia* by John Hooper of Queensland Museum, South Brisbane, Australia (QM species no. 2128).

Voucher specimen R1644 was deposited at ORSTOM center in Noumea. The sponge was found growing on sides of coral heads, in gullies, and on walls of coral reefs, at 10–35 m depth. It has a thickly encrusting lobate ridge-like growth form, spreading over the coralline substrate. Alive, the sponge is light gray with a mauve tinge, but gray in EtOH. There are numerous, discrete oscules up to 5 mm in diameter, regularly distributed over the surface, with slightly raised membranous lip and slightly raised on papillae, about 3–8 mm high. The sponge is firm and springy, but only slightly compressible. The surface ornamentation is described as opaque, membranous, optically smooth; it has uneven, microconulose goose-flesh. The ectosomal skeleton is slightly arenaceous with a thin scattering of fine sand-grains and spicule detritus; surface membrane was pushed up into microconules by ascending choanosomal fibres. The choanosomal skeleton is composed mainly of a regular reticulation of secondary spongin fibers infrequently interconnected by finer tertiary fibers. Primary fibers are reduced in number and occur throughout the choanosome, partially cored by sand detritus, whereas secondary and tertiary fibers are completely clear. Fibers are moderately well developed and lack any sign of lamination. Mesohyl collagen is moderately light and homogeneous, containing scattered sand grains and spicule detritus only in peripheral regions.

This species is clearly a member of the widely distributed genus *Spongia*, in having a reduced primary fiber system (cored by foreign debris) and a highly developed secondary network of fine, intertwined fibers making up the bulk of the skeleton (clear of any coring material) (Bergquist, 1980). Unfortunately, there are many, possibly hundreds of, species of *Spongia*, some of which are described in the literature and certainly many still undescribed. Furthermore, many of those known to science were described nearly a century ago, with descriptions poor by today's standards and type material scattered all over the world. This particularly applies to the many species of *Spongia* (and its synonym *Euspongia*) described by von Lendenfeld at the end of the 1800s, many of which were collected from Australasian waters. Until these ancient species are reexamined and reconciled with those collected more recently, with underwater observations pertaining to their living characteristics, it is not possible to name the present species. Nevertheless, this species shows some similarities to *Spongia reticulata* (Lendenfeld, 1885) from New South Wales (and allegedly also from New Zealand), but differs in that the latter has a much more prominently conulose surface, fewer larger oscules grouped around a central pore area, "shaggy" fiber endings around oscules, and a massive cushion shape. The fiber network and fiber diameter are otherwise similar between the two species, with the present one possibly new to science.

Extraction and Isolation. Preliminary assays for cytotoxic activity showed marked activity for the ethanolic extract (KB cells, 96% inhibition at 10 μ g/mL). The organisms were freeze-dried, and the lyophilized material (1.0 kg) was extracted with MeOH (3 \times 2 L) at room temperature. The extracts were combined and partitioned according to the modified Kupchan¹⁴ procedure as follows.

The methanol extract (80 g) was dissolved in a mixture of MeOH–H₂O containing 10% H₂O and partitioned against *n*-hexane. The water content (% v/v) of the MeOH extract was adjusted to 20% and 40%, and partitioned against CCl₄ and CHCl₃, respectively. The aqueous phase was concentrated to remove MeOH and then extracted with *n*-butanol. The bioactive chloroform extract (3.2 g) was chromatographed by DCCC using CHCl₃–MeOH–H₂O (7:13:8) in the ascending mode (the upper phase was the stationary phase).

Fractions 19–30 (380 mg) were purified by HPLC on a C₁₈ μ -Bondapak column (30 cm \times 3.9 mm i.d.) with MeOH–H₂O 70% to yield pure petrosaspongiolide D (**1**) (10 mg), petrosaspongiolide G (**2**) (7.0 mg), compound **3** (5.0 mg), compound **4** (8.0 mg), spongidine A (**5**) (3.0 mg), spongidine B (**6**) (2.8 mg), spongidine C (**7**) (1.2 mg), and spongidine D (**8**) (3.0 mg).

Compound 3: [α]_D –37.1° (c 0.015, MeOH); ¹H NMR (CD₃OD) δ _H 6.58 (1H, br s, H-24), 3.73–3.38 (2H, d, $J = 12.0$, H₂-21), 3.09–2.97 (2H, d, $J = 15.6$, H₂-18), 2.43 (1H, br t, $J =$

10.4, H-13), 2.37 (1H, dd, $J = 16.0, 3.7$, H-15), 2.23 (1H, t, $J = 16.0$, H-15), 2.04–1.22 (2H, H₂-12), 1.83–0.93 (2H, H₂-3), 1.76–0.88 (2H, H₂-1), 1.75–1.02 (2H, H₂-7), 1.72–1.49 (2H, H₂-11), 1.69–1.47 (2H, H₂-6), 1.62–1.42 (2H, H₂-2), 1.54 (1H, H-14), 1.02 (1H, H-5), 0.95 (3H, s, Me-20), 0.94 (3H, s, Me-23), 0.93 (1H, H-9), 0.89 (3H, s, Me-22); ^{13}C NMR (CD_3OD) δ_{C} 202.8 (C-16), 178.5 (C-19), 154.4 (C-24), 135.4 (C-17), 65.0 (C-21), 61.0 (C-9), 58.8 (C-5), 55.7 (C-14), 41.6 (C-7), 41.3 (C-1), 40.0 (C-4), 38.7 (C-18), 38.6 (C-15), 38.6 (C-10), 38.2 (C-13), 37.8 (C-8), 36.8 (C-3), 34.1 (C-12), 27.8 (C-20), 21.8 (C-11), 19.6 (C-6), 19.3 (C-2), 17.6 (C-22), 15.7 (C-23), HMBC H-5/C21, C22; H-15/C13, C14, C16, C17; H₂-18/C17, C24, C19, C16; H₃-20/C3, C4, C5, C21; H₂-21/C20, C3, C4, C5; H₃-22/C10, C1, C5, C9; H₃-23/C8, C7, C14, C9; H-24/C12, C14, C18, C16.

Compound 4: $[\alpha]_{\text{D}} -14.3^\circ$ (c 0.015, MeOH); ^{13}C NMR (CD_3OD) δ_{C} 173.4 (C-19), 164.7 (C-17), 118.2 (C-18), 101.8 (C-24), 95.5 (C-25), 73.0 (C-16), 65.1 (C-21), 61.1 (C-9), 58.5 (C-5), 53.4 (C-14), 42.4 (C-13), 41.2 (C-1), 40.2 (C-10), 38.5 (C-4), 39.7 (C-7), 37.6 (C-8), 36.7 (C-3), 30.7 (C-15), 29.5 (C-12), 27.6 (C-20), 20.7 (C-11), 19.6 (C-6), 19.2 (C-2), 17.3 (C-22), 15.3 (C-23); ^1H NMR (CD_3OD) δ_{H} 6.09 (1H, br s, H-25), 5.02 (1H, d, $J = 3.1$ Hz, H-18), 4.37 (1H, d, $J = 8.0$ Hz, H-24), 4.36 (1H, ddd, $J = 11.0, 2.2, 2.2$, H-16), 3.74–3.39 (2H, d, $J = 11.7$ Hz, H₂-21), 1.00 (3H, s, Me-20), 0.94 (3H, s, Me-22), 0.93 (3H, s, Me-23).

Spongidine A (5): $[\alpha]_{\text{D}} -16.2^\circ$ (c 0.010, MeOH); ^1H and ^{13}C NMR, see Table 1.

Spongidine B (6): $[\alpha]_{\text{D}} +7.8^\circ$ (c 0.012, MeOH); ^{13}C NMR (CD_3OD) δ_{C} 173.3 (CH_3CO), 170.4 (C-14), 169.9 ($-\text{CH}_2\text{COOH}$), 146.4 (C-21), 143.3 (C-16), 137.7 (C-13), 124.8 (C-15), 68.2 (C-17), 63.9 ($-\text{CH}_2\text{COOH}$), 57.7 (C-5), 54.8 (C-9), 40.8 (C-1), 40.4 (C-8), 39.6 (C-10), 38.9 (C-7), 38.2 (C-4), 37.4 (C-3), 28.6 (C-12), 27.8 (C-18), 25.6 (C-20), 20.9 (COCH_3), 20.1 (C-6), 19.2 (C-2), 18.0 (C-11), 17.4 (C-19); ^1H NMR (CD_3OD) δ_{H} 4.36–3.98 (2H, d, $J = 11.0$ Hz, CH_2 -17), 2.08 (3H, s, COCH_3), 1.06 (3H, s, Me-18), other signals are superimposable on those reported for 5.

Spongidine C (7): $[\alpha]_{\text{D}} -10^\circ$ (c 0.012, MeOH), ^{13}C NMR (CD_3OD) δ_{C} 179.4 (C-19), 170.4 ($-\text{CH}_2\text{COOH}$), 168.4 (C-14), 157.4 (C-16), 147.3 (C-24), 137.5 (C-13), 123.5 (C-15), 64.2 ($-\text{CH}_2\text{COOH}$), 57.5 (C-5), 55.9 (C-9), 43.2 (C-3), 40.6 (C-1), 40.2 (C-7), 39.6 (C-10), 39.5 (C-8), 36.2 (C-18), 34.3 (C-4), 33.8 (C-21), 33.2 (C-17), 28.4 (C-12), 25.9 (C-23), 21.9 (C-20), 20.0 (C-2), 19.7 (C-6), 18.3 (C-11), 17.0 (C-22); ^1H NMR (CD_3OD) δ_{H} 5.15 (2H, s, $-\text{CH}_2\text{COOH}$), 3.09 (1H, dd, $J = 18.0, 6.2$ Hz, H-12), 2.93 (1H, m, H-12), 1.32 (3H, s, Me-23), 1.03 (3H, s, Me-22), 0.94 (3H, s, Me-20), 0.93 (3H, s, Me-21).

Spongidine D (8): $[\alpha]_{\text{D}} -6^\circ$ (c 0.016, MeOH); ^1H and ^{13}C NMR, see Table 2.

Acknowledgment. This contribution is part of the ECC project Marine Sciences and Technology MAST III Contract MAS 3-CT95-0032. NMR, IR, UV, and MS spectra were

performed at "Centro Interdipartimentale di Analisi Strumentale", Università di Napoli "Federico II". The assistance of the staff is gratefully appreciated. We acknowledge the government of Vanuatu for giving us the authorization to collect samples there and the Fisheries department for their assistance. We thank Dr. John Hooper (Queensland Museum, Brisbane, Australia) for the identification of the sponge. This work was supported by grants from MURST (PRIN '97) "Chimica dei composti organici di interesse biologico", Rome, Italy, and CICYT (SAF98-0119), Spanish Ministerio de Educación y Ciencia. L.F.O. was the recipient of a Research Fellowship from the ALFA Program of European Union at the University of Valencia.
