al-metal bonded M^{II}₂ state with metal-separated M^{III}₂, M = Rh or Ir), we have identified a transformation that results in a "boat": "chair" rearrangement.

Mononuclear (pentamethylcyclopentadienyl)(pyrazole) complexes of Rh and Ir have recently been prepared by us as well as by others.⁶ Addition of NEt₃ to a solution in CH₂Cl₂ of orange Rh(η^5 -C₅Me₅)Cl₂(pzH) (4), followed by stirring (2 h), elution from a short alumina column using 20:1 CH₂Cl₂/MeOH, redissolution, and then precipitation with Et₂O afforded⁷ [Rh(η^5 -C₅Me₅)Cl(μ -pz)]₂ (5, 81% yield), the molecular geometry of which (as established⁸ by using X-ray crystallography) is illustrated as Figure 1, top. After treatment of compound 5 with AgBF₄ in acetone solution, a white precipitate formed, which was removed by filtration; subsequent introduction of Et₂O by vapor diffusion led to crystallization (95%) of the known⁶ dirhodium species $[Rh_2(\eta^5-C_5Me_5)_2(\mu-pz)_2(\mu-Cl)]BF_4$ (6), the cation geometry for which⁹ possesses 2-fold symmetry and is shown in Figure 1, middle. During stirring (48 h) of an orange solution of compound 6 in MeOH with excess Zn dust and Cu sand (ca. 1:1), the mixture gradually turned black and then to a deep purple color: we attribute the latter to the dirhodium(II) complex $[Rh(\eta^5-C_5Me_5)(\mu-pz)]_2$ (7), although this product has not yet been isolated as a pure solid.

Starting from the precursor 10 [Rh(η^5 -C₅H₅)Cl₂]₂, similar strategy afforded (55%) the analogue¹¹ [Rh(η^5 -C₅H₅)Cl- $(\mu$ -pz)]₂ (8) of 5, a methanolic solution of which when stirred with excess Zn dust underwent an abrupt color change from orange to purple after 30 min. Filtration, evacuation, then extraction into Et₂O led to recovery of the bright purple analogue $[Rh(\eta^5-C_5H_5)(\mu-pz)]_2$ (9) of 7, which (unlike the latter) was obtained (ca. 20% yield) as crystals suitable for X-ray diffraction, 12 by sublimation in vacuo (95 °C): the molecular geometry is reproduced as Figure 1, bottom. Reaction of compound 9 with NOBF results in reoxidation to a red, cationic dirhodium nitrosyl¹³ $[Rh_2(\eta^5-C_5H_5)_2(\mu-pz)_2(\mu-NO)]BF_4$ (10, 50%), while treatment with I_2 in Et₂O yields the diiodo analogue [Rh(η^5 - C_5H_5 $I(\mu$ -pz)]₂ (11, 71% yield) of 8. Diiridium(III) ana-

least-squares refinement to yield R = 0.0799, $R_w = 0.0791$.

(13) This complex has also been structurally characterized by singlecrystal X-ray diffraction.

logues of compounds 5 and 6 have been isolated; reduction to a diiridium(II) species (cf. 7 or 9) is being pursued.

Compound 5 adopts a rigorously centrosymmetric "chair" conformation (Figure 1) for the bridging unit (to our knowledge this is paralleled¹⁴ in related chemistry only in two structures, those of $[Ti(\eta^5-C_5H_5)_2(\mu-pz)]_2$ and [Rh- $(\eta^5-C_5H_5)pz(\mu-pz)]_2$, with the two Rh(III) centers 4.059 (2) A apart; it is formally the dichlorine adduct of the dirhodium(II) complex 7 (cf. the relationship between 9 and 11), which we anticipate will possess a metal-metal bonded geometry folded into a "boat" shape like that confirmed for 9 (Rh-Rh = 2.657 Å, Figure 1). This supposition is supported by the close similarity between the electronic absorption spectra of 7 and 9, both of which contain lowenergy maxima (respectively at 560, 502 nm) attributable to a $\sigma:\sigma^*$ transition from a Rh₂ bonding HOMO. The "chair": "boat" rearrangement is represented explicitly by chloride abstraction from 5 to give 6 (Figure 1), while the reverse conformational change is implicit in the 9:11 conversion (i.e., assuming 11 is structurally analogous to 5). In crystals of complex 5 the pz heterocycles are within 1° of coplanarity, i.e., as they would be oriented in transition during ring inversion of the more familiar "boat" structures (vide supra). Such relationships imply that core conformational change is an energetically feasible mechanistic pathway in redox phenomena associated with 1-3 and could also be responsible for racemization of the inherently chiral molecular configuration² of 3, thereby limiting stereochemical usefulness of the latter.

Soluble Mono(pentamethylcyclopentadienyl)zirconium Hydrides: X-ray Structure of $(C_5Me_5)_2Zr_2(\mu-H)_3Cl_3(PMe_3)$

Johannes R. van den Hende, Bart Hessen, Auke Meetsma, and Jan H. Teuben'

Department of Chemistry, Rijksuniversiteit Groningen Nijenborgh 16, 9747 AG Groningen, The Netherlands

Received October 10, 1989

Summary: The 14-electron alkyl complex Cp 2r- $[(CH_2)_3NMe_2]Cl_2$ $(Cp^* = \eta^5-C_5Me_5)$, containing a chelating (dimethylamino)propyl ligand, reacts with H2 to form a soluble crystallizable mono-Cp* zirconium hydride with a complicated stoichiometry, tentatively formulated as "Cp*3Zr3H4Cl5". Reaction of this compound with PMe3 induces disproportionation, in which Cp*ZrCl₃(PMe₃) and $Cp^{\bullet}_{2}Zr_{2}(\mu-H)_{3}Cl_{3}(PMe_{3})$, the first early-transition-metal (μ -H)3-bridged dimer, are formed. An X-ray structure determination of this compound (space group $P2_1/c$, a =

15.599 (3) Å, b = 11.203 (3) Å, c = 16.862 (4) Å, $\beta =$ 103.27 (2)° at 130 K, Z = 4) showed that one Cp*ZrCl(PMe3)- and one Cp*ZrCl3- moiety are bridged by three hydride ligands, with Zr-H distances ranging from 1.92 (3) to 2.35 (5) Å and Zr-H-Zr angles from 85.9 (17) to 104.1 (19)°.

Attempts to produce mono(pentamethylcyclopentadienyl)zirconium and hafnium hydrides by hydrogenolysis of $Cp*M(alkyl)_nCl_{3-n}$ ($Cp*=\eta^5-C_5Me_5$) have until now produced only insoluble polymeric products, even when a Lewis base is coordinated to the alkyl complex or excess Lewis base is added to the mixture. 1,2 The use of bulky phosphido ligands in the starting materials affords complexes such as $\{Cp*Hf(R)[\mu-P(CMe_3)_2](\mu-H)\}_2$ (R = Cl, Me).² The isolation of soluble crystalline tetrameric [Cp*Hf(H)₂Cl]₄ from hydrogenolysis of the diene complex Cp*Hf(2,3-dimethyl-1,3-butadiene)Cl was therefore remarkable.³ Possibly the 2,3-dimethyl-2-butene produced in the hydrogenolysis initially remains coordinated to the hydrido species. This could prevent the hydride from polymerizing immediately and allow formation of welldefined crystallizable oligomers. This prompted us to study complexes containing Lewis base substituted alkyl ligands that can remain (weakly) bound to the metal after hydrogenolysis of the M-C bond. Here the synthesis of (dimethylamino)propyl complexes of zirconium is described, as well as their use as precursors for soluble Cp*Zr hydrides.

In the reaction of Cp*ZrCl₃ with an excess of (dimethylamino)propyl Grignard reagent (0 °C), only two of the three chloride ligands are substituted to form the dialkyl monochloride complex Cp*Zr[(CH₂)₃NMe₂]₂Cl (1, eq 1). IR and low-temperature NMR spectroscopy4 show

Cp*ZrCl₃ + Me₂N(CH₂)₃MgCl (excess) →

$$\begin{array}{c|c} & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & & \\$$

that only one of the two dimethylamino groups is coordinated to the metal center at a time, indicating that I is sterically quite crowded. Comproportionation of 1 with Cp*ZrCl₃ in toluene (20 °C) produces in good yield (84%) in the 14-electron monoalkyl complex Cp*Zr-[(CH₂)₃NMe₂]Cl₂ (2, eq 1), in which the amino group is coordinated to the metal center. In the ¹H NMR spectrum, ⁴ 2 shows a single resonance for the amino methyl

(3) Booij, M.; Blenkers, J.; Sinnema, J. C. M.; Meetsma, A.; van Bol-

groups, without coalescence broadening even down to -70 °C. This indicates either a very rapid rotation and inversion of the NMe₂-group on NMR time scale or a pseudo-trigonal-bipyramidal geometry of the complex.

Reaction of 2 with H₂ (1 atm, 20 °C) in aromatic solvents forms a clear yellow solution from which large yellow crystals can be obtained by diffusion of pentane into the mixture. Full characterization of this product was hampered by facile loss of cocrystallized solvent from the crystal lattice (making the material unsuitable for X-ray analysis). IR spectroscopy ($\nu_{\rm Zr-H}$ = 1575, 1310, 1150, 901 cm⁻¹; $\nu_{\rm Zr-D}$ = 1136, 975, 802, 636 cm⁻¹ in the D₂ reaction product) does however indicate that a hydridic product has been formed. Low-temperature NMR spectroscopy⁵ suggests a complicated stoichiometry, " $Cp*_3Zr_3(H)_4Cl_5$ " (3), with four nonequivalent hydrides and three nonequivalent Cp* ligands. Elemental analysis does not provide much of a clue to the nature of 3 because for crystalline material varying Zr:Cl ratios are found (from 1.7 to 2.0), probably due to varying amounts of cocrystallized Cp*ZrCl₃ produced in the disproportionative formation of 3 (eq 2). Efforts to determine the structure of 3 are continuing.

$$\begin{aligned} &\operatorname{Cp*Zr}[(\operatorname{CH}_2)_3\operatorname{NMe}_2]\operatorname{Cl}_2 + \operatorname{H}_2 \to \\ & 2 \end{aligned} \\ & [\operatorname{Cp*Zr}(\operatorname{H})\operatorname{Cl}_2\cdot\operatorname{NMe}_2\operatorname{Pr}] \xrightarrow{-\operatorname{NMe}_2\operatorname{Pr}} \operatorname{``Cp*}_3\operatorname{Zr}_3(\operatorname{H})_4\operatorname{Cl}_5" \ \ (2) \end{aligned}$$

Reaction of 3 with PMe₃ induces further disproportionation, forming a dinuclear hydrido complex, $\operatorname{Cp*_{2}Zr_{2}(\mu-H)_{3}Cl_{3}(PMe_{3})}$ (4) and $\operatorname{Cp*ZrCl_{3}(PMe_{3})}$ (5, eq 3). The former can be obtained analytically pure as pale yellow crystals by slow crystallization from diethyl ether.

$$3\text{``Cp*}_{3}\text{Zr}_{3}(\text{H})_{4}\text{Cl}_{5}\text{''} + 5\text{PMe}_{3} \rightarrow \\ 4\text{Cp*}_{2}\text{Zr}_{2}(\mu\text{-H})_{3}\text{Cl}_{3}(\text{PMe}_{3}) + \text{Cp*ZrCl}_{3}(\text{PMe}_{3}) (3) \\ 4$$

An X-ray structure determination⁶ of 4 confirmed the triply hydride-bridged structure (Figure 1). It consists of one Cp*ZrCl(PMe3) and one Cp*ZrCl2 moiety in nearly eclipsed conformation (torsion angles P(1)-Zr(1)-Zr(2)- $Cl(3) = -11.34 (3)^{\circ}, CT(1)-Zr(1)-Zr(2)-Cl(2) = 6.29 (3)^{\circ},$ $Cl(1)-Zr(1)-Zr(2)-CT(2) = 28.38 (3)^{\circ}; CT(x) \text{ is the Cp*}$ centroid on Zr(x)), with three bridging hydrides staggered relative to the other ligands. The Zr(1)...Zr(2) distance of 3.126 (1) Å is considerably shorter than the 3.4599 (2) Å in the $(\mu-H)_2$ complex $[(\eta^5-C_5H_4Me)_2ZrH(\mu-H)]_2$, as is expected for a (µ-H)₃ dimer.⁸ The positions of the hydride ligands were determined unequivocally from the Fourier difference map and refined isotropically. The Zr-H distances to H(3) are longer than those for the other two H atoms, and the Zr(1)-H(3)-Zr(2) angle is very acute (85.9)

Reflections (5557) with $1.2 \le \theta \le 28^{\circ}$ and $I \ge 2.5\sigma(I)$ were considered observed. All hydrogen atoms were located in the Fourier difference map and refined isotropically. R = 0.034, $R_w = 0.039$ ($w = [\sigma^2(F)]^{-1}$) for 432

At 75 °C only one μ -H resonance is observed at 4.09 ppm (br, 3 H); 31 P NMR (121.4 MHz, toluene- d_8 , -30 °C, PMe₃ protons selectively decoupled) δ -18.1 (ddd, $^2J_{PH} = 18.3$, 12.1, 8.3 Hz). At 75 °C a quartet is observed ($^2J_{PH} = 12.9$ Hz).

(6) 4 crystallizes in the monoclinic space group P_{21}/c with a = 15.599 (3) Å, b = 11.203 (3) Å, c = 16.862 (4) Å, $\beta = 103.27$ (2)° (130 K), Z = 4. Reflections (5557) with 1.2 $\leq \theta \leq 28$ ° and $I \geq 2.5\sigma(I)$ were considered

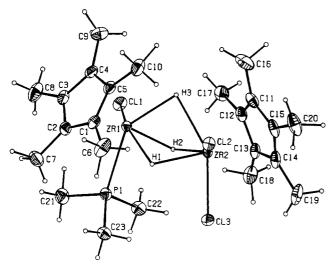

Figure 1. Molecular structure of $Cp_2Zr_2(\mu-H)_3Cl_3(PMe_3)$ (4). Selected structural parameters are as follows: Zr(1) - Zr(2) = 3.126 (1), Zr(1) - Cl(1) = 2.470 (1), Zr(2) - Cl(2) = 2.456 (1), Zr(1) - Zr(= 2.452 (1), Zr(1)-P(1) = 2.744 (1), Zr(1)-H(1) = 1.92 (3), Zr-(1)-H(2) = 2.00(3), Zr(1)-H(3) = 2.24(5), Zr(2)-H(1) = 2.04(4), $Zr(2)-H(2) = 1.98(3), Zr(2)-H(3) = 2.35(5) \text{ Å}, \angle Zr(1)-H(1)-Zr(2)$ = 104.1 (19), $\angle Zr(1) - H(2) - Zr(2) = <math>103.2 (14)$, $\angle Zr(1) - H(3) - Zr(2)$ = 85.9 (17), $\angle P(1) - Zr(1) - Cl(1) = 86.06$ (3), $\angle Cl(2) - Zr(2) - Cl(3) = 86.06$ 101.77 (3)°

(2)°, compare Hf-H-Hf of 94 (5)° in $\{Cp*Hf(Me)[\mu-P-m]\}$ $(CMe_3)_2$](μ -H) $_2^2$). At -30 °C the ¹H NMR spectrum⁵ of 4 shows three nonequivalent hydride resonances, each with one $^2J_{\rm PH}$ and two (equivalent) $^2J_{\rm HH}$ couplings. At 75 °C all hydride signals are coalesced into one broad resonance, indicating rapid interchange of the hydrides at higher temperatures. Since at this temperature two different Cp* resonances remain, rapid exchange of Cl and PMe3 between the metal centers apparently does not occur. Compound 4 is the first example of a $(\mu-H)_3$ -bridged earlytransition-metal dimer. In the heterobimetallic complex Cp₂Zr(Cl)(H)₃Os(PMe₂Ph)₃⁹ the metal centers are probably also (μ -H)₃ bridged, although the hydrides could not be located by X-ray diffraction. A number of late-transition-metal $(\mu$ -H)₃ complexes are known (such as $[Fe_2(\mu$ - $H_{3}(triphos)_{2}$ [PF₆] and related compounds¹⁰).

Despite the difficulties encountered in the characterization of 3, the use of the (dimethylamino) propyl ligand has enabled us to obtain soluble, crystalline Cp*Zr hydrides. This makes it likely that intermediate stabilization of the newly formed hydride by an (already coordinated) weak Lewis base is essential to the formation of soluble complexes. For these sterically and electronically strongly unsaturated hydrides, the formation of thermodynamically favored oligomers with bridging hydride ligands is the driving force for the observed disproportionation to give complexes with complicated stoichiometries. Bercaw et al. already observed that in the hydrogenolysis of Cp*Hf[P(CMe₃)₂]Cl₂ an intermediate Cp*Hf(H)Cl₂ species can be trapped with ethene² but in the absence of trapping agents probably disproportionates. This contrasts with the behavior of (sterically more encumbered) monomeric electron-deficient complexes, where the thermodynamic bias toward dispersion of π -donor ligands (like halides or alkoxides) promotes comproportionation rather than disproportionation.¹¹ Presently we are investigating a range of Cp*M hydrides (M = Zr, Hf) with varying stoichiometries and their interaction with Lewis bases to get a more complete view of the structure-determining factors in strongly electron-deficient early-transition-metal hydrides.

Received October 20, 1989

Summary: The acyl(carbonyl) complex cis-[Pt(COPh)-(CO)(PPh₃)₂]⁺ (2a) reacts with PhLi to yield the neutral dibenzoyl complex cis-Pt(COPh)2(PPh3)2 (3a) in 34% isolated yield. The crystallographic data of 3a indicate that it is disposed in a distorted square-planar geometry with two benzoyl carbonyls in the s-trans configuration. The analogous reaction of the cationic 2a with MeLi, however, gives three products: cis-Pt(COPh)(COMe)(PPh3)2 (3b), cis-Pt(COPh)(Me)(PPh₃)₂ (4), and Pt(COPh)(Me)(CO)(PPh₃) (5a) in a relative ratio of 1:2.5:3 in 55% total yield. In a similar reaction carried out in the presence of extra PPh₃, only 3b and 4 were obtained, in a 1:3.5 ratio in 90% total yield. The structures of the complexes 4 and 5a were determined by X-ray crystallography, and both are square planar. In 5a, the PPh3 was found trans to the benzoyl ligand. The replacement of a PPh3 in 4 by CO gives 5a and its regio isomer 5b, whose PPh3 is instead trans to the methyl group. The complex 5b is kinetically favored but thermodynamically unstable. These substitution reactions are reversible with the equilibria in favor of 4.

The rare diacyl complexes of the prototype RC(O)MC-(O)R' (wherein R and R' are hydrocarbyls) are either anionic^{1,2} or are stabilized by bridging structures.²⁻⁴ Curi-
